UPS Archive Scanning and Metasploit 4.Bash on Windows, or BOW, is a free open-source implementation of the Bourne-again shell), which first came into the public eye in August 2002, when it was announced in a Usenet posting by a hacker named Aristide Genet, with the goal of porting the Bourne shell to Windows, where it would run on Windows-native machine code. The project proved popular with users, so the project was continued by Genet in 2003 and 2004, and since then there have been frequent releases of new versions of BOW, with the most recent release, v1.12.0, on 5 January 2016. The latest BOW release features improvements to features which had been implemented in the shell via the libtinfo project, such as various bashisms and improved compatibility with other shells such as tcsh, zsh, and csh. It is available as source code on GitHub, and is an open-source project under a BSD-like license. The functionality of BOW is significantly more extensive than the original version; it supports full POSIX-like compatibility, including case sensitivity, the ability to change the way certain strings are split, lexical substitution, pathname expansion, commands which run in subshells, and other features. The portability of BOW is maintained through the use of a bytecode interpreter (a.k.a. shellcode), which windows such as Ada, have been created. History As reported by Bleeping Computer, the original announcement by Aristide Genet described a shell called "zsh on Windows" which was a port of the zsh project had developed a portable version of the Bourne shell) when they were used on the same partition, with no problems with the ext3 filesystem (which had previously been required for the execution of the Bourne shell).

Later versions of the zsh project provided a version which could be ported to FAT16 and NTFS filesystems, and eventually to all file
